

## Review Week 5

- Key exchange
  - 3rd party solution (TTP)
- Generating keys
  - x shared key with y
    - eavesdropping security only
    - x contains  $k_a$
    - y contains  $k_b$
    - eavesdropper learns nothing about  $k_{ab}$
- Toy protocol
  - insecure against active attackers
    - replay attack - attack records session between x and y then replays the session to y
- Merkle Puzzle
  - key exchange without a TTP
  - puzzle
    - $\text{puzzle}(P) = E(P, \text{"message"})$
    - $P = 0^{96} || b_1 \dots b_{32}$
    - Alice
      - prepares  $2^{32}$  puzzles
      - For  $i = 1$  to  $2^{32}$  choose random  $P_i$  element of  $\{0,1\}^{32}$  and  $x_i, k_i$  element  $\{0,1\}^{128}$
      - $\text{puzzle}_i = E(0^{96} || P_i || k_i)$
      - send all the puzzles to Bob
    - Bob
      - choose random  $\text{puzzle}_j$  and solves it
      - obtains  $(x_j, k_j)$  and solves it
      - sends  $x_j$  to Alice
    - Alice
      - lookup puzzle with number  $x_j$ . Use  $k_j$  as shared secret
- Merkle Puzzles
  - Alice's and Bob's work  $O(n)$  each
  - Eavesdropper's work  $O(n^2)$
- Diffie-Hellman protocol
  - Fix a large prime  $p$
  - Fix an integer  $g$  in 1 to  $p$
  - Alice and Bob
    - Alice choose random  $a$  in 1 to  $p - 1$
    - Bob choose random  $b$  in 1 to  $p - 1$
    - Alice sends  $A \leftarrow g^a \pmod{p}$
    - Bob sends  $B \leftarrow g^b \pmod{p}$
    - Shared key  $= k_{ab} = g^{ab} \pmod{p}$
  - Eavesdropper sess:  $p, g, A$ , and  $B$ 
    - $DH(g^a, g^b) = (g^{ab}) \pmod{p}$
    - How hard is the function to compute
- Man in the middle attack
  - DH insecure against active attacks
  - Intercept message and send own values  $a'$  and  $b'$
- Public key encryption
  - $G()$ : randomized algorithm outputs key pair  $(pk, sk)$

- $E(pk, m)$ : randomized algorithm that takes  $m$  element  $M$  and outputs  $c$  element  $C$
- $D(sk, c)$ : deterministic algorithm that takes  $c$  element  $C$  and outputs  $m$  element  $M$  or reject
- Consistency
- Semantic security
  - Two experiments the probability of outputting experiment 0 = 1 or experiment 1 = 1 is negligible
- Establishing a shared secret
  - Alice and Bob
    - Alice sends  $pk$  to Bob
    - Bob sends  $c \leftarrow E(pk, x)$  to Alice
    - Alice decrypts  $D(sk, c) \rightarrow x$
  - Adversary sees  $pk, E(pk, x)$  and wants  $x$  element  $M$
  - Semantic security
    - adversary cannot distinguish  $\{pk, E(pk, x), x\}$  from  $\{pk, E(pk, x), \text{rand element } M\}$
  - Can derive session key from  $x$
  - vulnerable to man in the middle
- Public key encryption: constructions generally rely on hard problems from number theory and algebra
- Number Theory see notes
